Overview

Project Atlas migrates the Lumen Labs analytics platform to a new data stack.

This version reflects the benchmark review of August and the backfill plan.

Event store

The event store uses PostgreSQL with monthly partitions. We decided on PostgreSQL rather than MongoDB because reporting queries are relational.

Retention is 25 months; older partitions move to object storage.

Backfill plan

Historical events from Northwind Analytics are loaded in daily batches.

Priya Nair validates row counts per table before each cutover step.

Risks

Multi-region requirements from customers could force a different event store.

The migration runbook must be complete before the launch date.
